

Prescribed Burning

The use of fire in land management is important and must be performed by an experienced professional to insure the protection of the property and the public. We have been performing such work for 30-years under both ideal and extreme conditions. Following all safety protocol is critical to a successful burn.

Whether the goal is to clean a timber stand after thinning or removal of large piles from site clearing, respect for the changing site conditions, public access and desirable native plants to preserve is our priority. Proper use of fire can protect and release native plants from the choking presence of invasive plants; giving the native habitat an opportunity to restore itself.

With patience and care the brush is burned without damaging the trees. Charred remnants will decay and leave the stand healthier and safer from wildfire as well.

Although spectacular to watch, night fires are serious and not undertaken lightly. This stand had to be burned and conditions were getting drier each day. At dusk the humidity would increase to a safe level and we were able to complete the burn without the fire jumping or getting into the crowns.

Burning a prairie or even a pasture requires constant attention and a lot of fire breaks to help maintain control of the site and allow us to put the fire out if conditions deteriorate.

This pond was built for the Army as part of a Wetland Mitigation Project in 2001 and has developed a forest. The pond is the original site showing the forest.

Safe disposal of debris from site clearing or tornado damage, is especially dangerous because of the possibility of windborne embers that pose a hazard to surrounding property. Being able to read the conditions and choose the safest time to burn is critical.

We have an outstanding safety record performing this work; protecting the property of our clients, keeping smoke off the roads and avoiding hazard to the surrounding landowners.
